

## 5G throughput prediction using space information

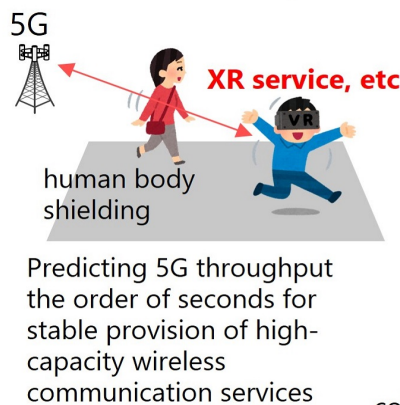

## Background

The use of high frequency bands such as millimeter waves is essential for high-capacity wireless communications, but these bands are influenced by surroundings. If the quality can be predicted and buffers etc. can be controlled, high-capacity communication services such as XR can be stably provided.

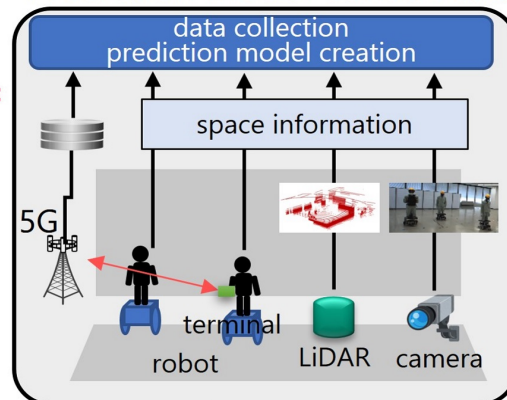

## Summary

For application to high-capacity wireless communications using the millimeter wave expected for 6G, we built a 5G verification environment and evaluated 28GHz 5G throughput prediction using space information such as the position and speed of terminals and surrounding objects.

## scenario example

## Prediction model construction

collection of space information such as position of terminals and Learning the relationship between space information and 5G throughput

## Prediction result

Throughput prediction in order of seconds

## Features

- We collected space information such as location and velocity of communication terminal and build a 5G verification environment that can evaluate 5G throughput
- We established 5G throughput prediction models based on deep learning using space information collected in the verification environment
- We confirmed and evaluated the rapid throughput degradation due to shielding effect in 28GHz 5G channel

## Future\_benefits

Proactive controls based on 5G throughput prediction allow user to stably use high-capacity wireless communication services without being aware of their terminals and surroundings.
